Abstract

In p -form lattice gauge theory, the fluctuating variables live on p -dimensional cells and interact around $(p + 1)$ -dimensional cells. It has been argued that the continuum version of this model should be described by $(p - 1)$ -gerbes. However, only connections and curvatures for gerbes are understood, not covariant derivatives. Using the lattice analogy, an alternative definition of gerbes is proposed: sections are functions $\phi(x, s)$, where x is the base point and s is the surface element. In this purely local formalism, there is a natural covariant derivative. The Yang-Baxter equation, and more generally the simplex equations, arise as zero-curvature conditions. The action of algebras of vector fields and gerbe gauge transformations, and their abelian extensions, are described.

1 Introduction

Gerbes have recently attracted considerable attention. Apart from being of intrinsic mathematical interest [9, 10, 15], they appear in Hamiltonian quantization [12] and in brane models [11, 29]. There also seem to be close ties between gerbes and n -category theory [5, 13]

My interest in this subject arose when I tried to understand lattice integrable statistical models. As is well known, the quantum Yang-Baxter equation (QYBE) is a sufficient (and in practise necessary) condition integrability in two dimensions [6]. The analogous sufficient condition in three dimensions is Zamolodchikov's tetrahedron equation [4, 8, 7, 28], and in n dimensions it is the so-called n -simplex equation. Unfortunately, very few

solutions to the tetrahedron equation are known, and those that are known do not depend on any temperature-like parameters.

Long ago I observed a striking similarity between the QYBE and the zero-curvature condition in lattice gauge theory. This lead me to formulate a statistical model where the fluctuating variables live on plaquettes rather than links [18]. In section 2 this model is reviewed, and a serious flaw is corrected: it is necessary to assign several variables to each plaquette. An important feature of this model is that the gauge-invariant holonomy is given by two-dimensional “Wilson surfaces”. The generalization to higher-dimensional models is now obvious: the variables live on p -cells and there is holonomy associated to p -dimensional “Wilson submanifolds”.

The continuum limit of this kind of model is p -form electromagnetism in the abelian case, and in general it is a gauge theory on loop space. The first such model was probably written down by Freund and Nepomechie [14], but already a few years before had Polyakov noted that ordinary gauge theory can be formulated as a sigma model in loop space [25, 26]. This immediately suggests that continuum integrability in higher dimensions is best understood in terms of flat connections on gerbes, which is closely related to BF theory [1].

Whereas a theory of connections on abelian gerbes has been around for a few years [15, 19], the situation for non-abelian gerbes is very tentative. Various suggestions, whose mutual relations are unclear to me, can be found in [2, 3, 9, 20]. What does not seem right, neither from the loop space approach or from lattice gauge theory, is the appearance of a hierarchy of connections. Another problem with the gerbe and BF approaches is that there seems to be no natural covariant derivative. This is a serious drawback since the main interest in connections is their relation to parallel transport. The standard approach to gerbes is reviewed in Section 3.

To remedy these problems, I suggest an alternative definition of gerbes in Section 4. The main idea is that a gerbe section $\phi(x, s)$ is a function not only of the spacetime point $x \in \mathbb{R}^n$, but also a function of the direction s . A gerbe section is a functional on loops over $\mathbb{R}^n$, the local information about which is encoded in the point x and the direction s of the loop passing through x . The generalization to higher gerbes is obvious, and in fact we mainly formulate the results for 2-gerbes. In this way, a manifestly local tensor calculus is developed, which should be useful for explicit calculations. We construct covariant derivatives, connections and curvatures and check that all constructions are invariant both under infinitesimal spacetime diffeomorphisms and under gerbe gauge transformations.

Flatness of the gerbe connection gives rise to the classical Yang-Baxter

equation in a particular gauge, which again indicates relevance for higher-dimensional integrability. Finally, it is shown how p -form electromagnetism can be recovered in the abelian case. The language developed in the present paper is thus appropriate for the non-abelian generalization of p -form electromagnetism, which is known to be impossible using ordinary bundles [27].

I thank Peter Orland for pointing out early references [21, 22, 23, 24], where lattice models very similar to that in Section 2 were constructed.

2 A generalization of lattice gauge theory

Recall that in ordinary lattice gauge theory [16], the amplitude for parallel transport along a link from x to $x + \hat{\mu}$ is the matrix

$$U_{\mu}(x) = \exp(iaA_{\mu}(x)), \quad (2.1)$$

where a is the lattice spacing and A_{μ} is the μ :th component of the gauge potential. Here $x \in \mathbb{Z}^n$ is a point on an n -dimensional hypercubic lattice and $\hat{\mu}$ denotes a unit vector in the μ :th direction. If a particle is transported along a link and then back again, nothing has happened, so we associate the matrix $U_{-\mu}(x + \hat{\mu}) = U_{\mu}^{-1}(x)$ with the same link with the opposite orientation. The curvature is given by the holonomy around a plaquette, which is the smallest loop that can be constructed.

$$U_{\mu}(x)U_{\nu}(x + \hat{\mu})U_{\mu}^{-1}(x + \hat{\nu})U_{\nu}^{-1}(x) = \exp(ia^2F_{\mu\nu}(x)). \quad (2.2)$$

The action reads

$$\sum_{\text{plaquettes}} \text{tr} UUUU + h.c. = \text{const} + a^2 \int d^n x F_{\mu\nu}(x)F^{\mu\nu}(x) + O(a^3). \quad (2.3)$$

We see that in the limit that the lattice spacing $a \rightarrow 0$, this becomes the Yang-Mills action, at least formally. There is a gauge symmetry associated to each vertex; the transformation

$$U_{\mu}(x) \rightarrow f^{-1}(x + \hat{\mu})U_{\mu}(x)f(x) \quad (2.4)$$

leaves the action (2.3) invariant. The gauge invariant observables are Wilson loops, i.e. the product of matrices around a closed loop.

Instead of putting matrices on links, it is natural to put four-index quantities on plaquettes. Associate a vector space V to each link, and an element $U_{\mu\nu} \in \text{End}(V_{\mu} \otimes V_{\nu})$ to a plaquette in the $\mu\nu$ -plane. $U_{\mu\nu}$ is in fact an element

Figure 1: Upper row: $U_\mu^L(x)$ and $U_\mu^R(x + \hat{\mu}) = [U_\mu^L(x)]^{-1}$.
Middle row: $U_{\mu\nu}^{NE}(x)$ and $U_{\mu\nu}^{SW}(x + \hat{\mu} + \hat{\nu}) = [U_{\mu\nu}^{NE}(x)]^{-1}$.
Lower row: $U_{\mu\nu}^{SE}(x + \hat{\nu})$ and $U_{\mu\nu}^{NW}(x + \hat{\mu}) = [U_{\mu\nu}^{SE}(x + \hat{\nu})]^{-1}$.

acting on $V \otimes V \otimes \dots \otimes V = V^{\otimes n}$, where n is the number of dimensions, but it acts as the identity except on the μ :th and ν :th factors. We can interpret $U_{\mu\nu}(x)$ as the amplitude for parallel transport of a string element across the plaquette.

In fact, and this is something which I missed in [18], two independent variables are needed for each plaquette. $U_{\mu\nu}(x) \equiv U_{\mu\nu}^{NE}(x)$ can be interpreted as the amplitude for parallel transport of a string element across the NE diagonal, as illustrated in Figure 1. It is then clear that four such amplitudes are needed, one each for the four different directed diagonals. However, only two amplitudes are independent, since $U_{\mu\nu}^{SW}(x + \hat{\mu} + \hat{\nu}) = [U_{\mu\nu}^{NE}(x)]^{-1}$ and $U_{\mu\nu}^{SE}(x + \hat{\nu}) = [U_{\mu\nu}^{NW}(x + \hat{\mu})]^{-1}$.

To every triangulated surface Σ , we can associate a holonomy $W(\Sigma)$

Figure 2: Associativity. The amplitude of parallel transport across a 2×2 square is independent of the intermediate steps.

by contracting indices associated to links were two plaquettes are glued together. This holonomy is the amplitude for transport of a string across the surface. As we see in Figure 2, there is a natural notion of associativity. Since we now have a vector space V_ℓ associated to each link ℓ on the boundary of the Wilson surface,

$$W(\Sigma) \subset \bigotimes_{\ell \in \partial \Sigma} V_\ell. \quad (2.5)$$

The curvature is the infinitesimal holonomy associated to each elementary cube. E.g., for a cube in the 123-direction one has

$$UUUUUU = U_{12}(x)U_{13}(x)U_{23}(x)[U_{12}(x + \hat{3})]^{-1}[U_{13}(x + \hat{2})]^{-1}[U_{23}(x + \hat{1})]^{-1} \quad (2.6)$$

and the action reads

$$\sum_{\text{elementary cubes}} \text{tr } UUUUUU + 7 \text{ more terms.} \quad (2.7)$$

The eight terms corresponds to the cube's eight directed diagonals. Just as the two terms in ordinary lattice gauge theory can be interpreted as parallel transport of a particle around the plaquette, in the clockwise and counter-clockwise directions, the eight terms here rotate a string piece around the cube's diagonals.

There is a gauge symmetry associated to each link; the transformation

$$U_{\mu\nu}(x) \rightarrow [f_\mu(x + \hat{\nu})]^{-1}[f_\nu(x + \hat{\mu})]^{-1}U_{\mu\nu}(x)f_\mu(x)f_\nu(x) \quad (2.8)$$

Figure 3: The curvature is the amplitude for parallel transport of string element around a cube.

Figure 4: Commutativity $U_1 U_2 = U_2 U_1$ and the Yang-Baxter equation $U_{12} U_{13} U_{23} = U_{23} U_{13} U_{12}$.

leaves the action invariant. The gauge invariant observables are closed Wilson surfaces, i.e. the product of four-index objects around a closed, two-dimensional surface. The natural continuum formulations of this model are in terms of loop or membrane variables (non-zero and zero curvature, respectively). Locality is not manifest in these formulations, but it is clear on the lattice that the model is perfectly local; the action is a sum over elementary cubes.

The zero-curvature condition is quite interesting. In the spatially homogeneous case (objects depend on orientation but not on location), zero 1-curvature becomes $U_1 U_2 U_1^{-1} U_2^{-1} = 0$, i.e. U_1 and U_2 commute. Vanishing 2-curvature becomes

$$U_{12} U_{13} U_{23} = U_{23} U_{13} U_{12}, \quad (2.9)$$

which is the Yang-Baxter equation, of paramount importance to the theory of integrable lattice models in two dimensions. The standard illustration of the Yang-Baxter equation is the equality of two cube halves, as shown in Figure 4.

It is immediate how to generalize this model to p -Yang Mills theory on the lattice. The zero p -curvature condition is known as the p -simplex equation. It is sufficient to construct integrable lattice models in p dimensions,

but unfortunately no interesting solutions to it are known. More precisely, some solutions are known, but one needs a continuum of solutions depending on variables like temperature or magnetic field to be able to compute critical exponents.

3 Gerbes

3.1 Bundles

Let us first review the definition of an ordinary line bundle over an n -dimensional manifold M . Start with a good cover of M . Each neighborhood U_a looks like $\mathbb{R}^n$, and on the overlaps $U_a \cap U_b$ we define transition functions g_{ab} with values in S^1 . We can illustrate each neighborhood by a $\bullet$ and the overlap, or rather the transition function, as an arrow between bullets:

$$\begin{array}{ccc} U_a & \xrightarrow{g_{ab}} & U_b \\ \bullet & \longrightarrow & \bullet \end{array}$$

The transition functions must satisfy the consistency conditions

$$\begin{aligned} 1) \quad & g_{ab}g_{ba} = 1, \\ 2) \quad & g_{ab}g_{bc}g_{ca} = 1, \end{aligned} \tag{3.1}$$

which can be illustrated by the following diagrams

$$\begin{array}{ccc} U_a & \xrightarrow{g_{ab}} & U_b \\ \bullet & \longrightarrow & \bullet \\ & \xleftarrow{g_{ba}} & \end{array}$$

$$\begin{array}{ccc} U_a & \xrightarrow{g_{ab}} & U_b \\ \bullet & \longrightarrow & \bullet \\ & \searrow g_{cb} & \nearrow g_{bc} \\ & \bullet & \\ & U_c & \end{array}$$

i.e. going round a triangle results in the unit operator. These conditions make g_{ab} into a Čech cocycle in $H^0(M, C^\infty(S^1))$.

Two manifolds g_{ab} and g'_{ab} are equivalent if there exist functions f_a on U_a such that

$$g'_{ab} = g_{ab}f_a^{-1}f_b \tag{3.2}$$

corresponding to the picture

$$\begin{array}{ccc} f_a^{-1} & g_{ab} & f_b \\ \bullet & \longrightarrow & \bullet \end{array}$$

This is already very reminiscent of a lattice gauge theory with neighborhoods playing the role of points and transition functions the role of amplitudes, and the equivalence relation is recognized as a gauge transformation.

3.2 Gerbes

A gerbe (more precisely, 1-gerbe) is a generalization of a bundle. On every triple overlap $U_a \cap U_b \cap U_c$ we define a function g_{abc} , which can be illustrated by the oriented triangle

The transition functions satisfy

$$g_{abc} = g_{bca} = g_{cab}^{-1} \quad (3.3)$$

and the cocycle condition on quadruple overlaps

$$g_{abc}g_{abd}^{-1}g_{acd}g_{bcd}^{-1} = 1. \quad (3.4)$$

This condition corresponds to a tetrahedron diagram. Two gerbes g_{abc} and g'_{abc} are equivalent if there are functions f_{ab} living on double overlaps (i.e. the edges of the triangle), such that

$$g'_{abc} = g_{abc}f_{ab}f_{bc}f_{ca}. \quad (3.5)$$

These conditions make g_{abc} into a Čech cocycle in $H^1(M, C^\infty(S^1))$. Again there is striking resemblance with the lattice 2-gauge theory I described: the transition function g_{abc} lives on a plaquette, there is a gauge invariance f_{ab} living on the link, and a curvature associated to a 3-dimensional cell.

The main difference is that two-form lattice gauge theory involves square plaquettes whereas the gerbe picture gives rise to triangles.

It is now straightforward to extend the definitions to p -gerbes in terms of functions living on $(p+2)$ -fold overlaps and satisfying cocycle conditions on $(p+3)$ -fold overlaps. In particular, bundles = 0-gerbes and gerbes = 1-gerbes.

3.3 Connections on abelian bundles

Define a one-form A_a on U_a and a global two-form F by

$$\begin{aligned} A_a - A_b &= d \log g_{ab} && \text{on } U_a \cap U_b \\ F &= dA_a && \text{on } U_a \end{aligned} \quad (3.6)$$

Two bundles g_{ab} and g'_{ab} with connections A_a and A'_a are equivalent if $g_{ab} \sim g'_{ab}$ with equivalence f_a (3.5) and

$$A'_a = A_a + d \log f_a \quad \text{on } U_a \quad (3.7)$$

3.4 Connections on abelian gerbes

Define a one-form $A_{ab} = -A_{ba}$ on $U_a \cap U_b$, a two-form F_a on U_a and a global three-form G .

$$\begin{aligned} A_{ab} + A_{bc} + A_{ca} &= d \log g_{abc} && \text{on } U_a \cap U_b \cap U_c \\ F_b - F_a &= dA_{ab} && \text{on } U_a \cap U_b \\ G &= dF_a && \text{on } U_a \end{aligned}$$

Two gerbes g_{abc} and g'_{abc} with gerbe-connections A_{ab} , F_a and A'_{ab} , F'_a are equivalent if $g_{abc} \sim g'_{abc}$ and

$$\begin{aligned} A'_{ab} &= A_{ab} + B_b - B_a - d \log f_{ab} && \text{on } U_a \cap U_b \\ F'_a &= F_a + dB_a && \text{on } U_a. \end{aligned}$$

Note the trade-off between overlap and spacetime indices (form degree).

3.5 Connection on non-abelian gerbes

The treatment of abelian gerbes seems rather well established. However, if one wants to identify the Yang-Baxter equation with a flatness condition for gerbe connection, one must consider non-abelian gerbes; the Yang-Baxter equation $R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12}$ is not very interesting if R_{ab} is abelian.

Mackaay [20] defines local one-forms $A_a \in U_a$, valued in the Lie algebra $\mathfrak{g}$ of G , such that

$$A_b - f_{ba}A_af_{ab} - d\log f_{ab} = A_{ab} \quad \text{on } U_{ab}. \quad (3.8)$$

Two gerbes f_{ab}, g_{abc} and f'_{ab}, g'_{abc} with connections A_a, A_{ab}, F_a and A'_a, A'_{ab}, F'_a are equivalent if there exists h_a such that

$$A'_a = h_a^{-1}A_ah_a + B_a + d\log h_a. \quad (3.9)$$

3.6 Local expressions for gerbe connections and curvatures

Locally, a bundle connection is a $\mathfrak{g}$ -valued one-form $A = A_\mu dx^\mu$ and the curvature is a $\mathfrak{g}$ -valued two-form $F = F_{\mu\nu}dx^\mu dx^\nu$, where $F = dA + [A, A]$. The Bianchi identity reads $dF + [A, F] = 0$.

Attal [3] introduces the following data¹ to describe a gerbe connection: a $\mathfrak{g}$ -valued one-form A (connection) and an $\mathfrak{der}(\mathfrak{g})$ -valued two-form B (curving), whose curvatures are given by a $\mathfrak{g}$ -valued two-form F and a $\mathfrak{der}(\mathfrak{g})$ -valued three-form G , where

$$\begin{aligned} F &= dA + [A, A] + B, \\ G &= dB + [A, B], \\ [B, B] &= 0. \end{aligned} \quad (3.10)$$

The Bianchi identity

$$dG + [A, G] = [F, B] \quad (3.11)$$

follows from $d^2 = 0$ and the Jacobi identity.

However, this formulation seems unsuitable to describe the generalized lattice model in Section 2, for several reasons.

- A hierarchy of connections arises in the continuum description but only the top $(p+1)$ -form connection appears on the lattice.

¹Attal uses different letters.

- The modified curvature $F' = F - B = dA + [A, A]$ is the usual curvature of the one-form connection A .
- There is no natural covariant derivative.
- There seems to be no natural place for the Yang-Baxter equation.

With these problems in mind, I propose an alternative local formulation of gerbes in the next section.

4 Gerbes in local coordinates

4.1 Symmetries

Locally, the gerbe coordinates are (x, s) , where $x = (x^\mu)$, $\mu = 1, 2, \dots, n$ is a point in the underlying space $\mathbb{R}^n$, and $s = (s^{\mu_1 \mu_2 \dots \mu_p})$, is a p -dimensional surface element. We have $s^{\mu_1 \dots \mu_i \dots \mu_j \dots \mu_p} = -s^{\mu_1 \dots \mu_j \dots \mu_i \dots \mu_p}$. For definiteness, we will mainly consider the case $p = 2$ in the sequel, but all formulas are readily generalized to arbitrary p , and later the case $p = 1$ will receive special attention. Introduce derivatives $\partial_\mu = \partial/\partial x^\mu$ and $\tilde{\partial}_{\mu\nu} = \partial/\partial s^{\mu\nu}$, satisfying the Heisenberg algebra

$$[\partial_\nu, x^\mu] = \delta_\nu^\mu, \quad [\tilde{\partial}_{\rho\sigma}, s^{\mu\nu}] = \delta_\rho^\mu \delta_\sigma^\nu - \delta_\sigma^\mu \delta_\rho^\nu. \quad (4.1)$$

Let $\xi = \xi^\mu(x) \partial_\mu$ be a vector field acting on the base space $\mathbb{R}^n$. The algebra of vector fields $\mathfrak{vect}(n)$, i.e. the algebra of infinitesimal diffeomorphisms, can be realized as

$$\begin{aligned} \mathcal{L}_\xi &= \xi^\mu(x) \partial_\mu + \partial_\nu \xi^\mu(x) s^{\nu\rho} \tilde{\partial}_{\mu\rho} + \partial_\nu \xi^\mu(x) T_\mu^\nu \\ &= \xi^\mu(x) + \partial_\nu \xi^\mu(x) \tilde{T}_\mu^\nu, \end{aligned} \quad (4.2)$$

where both

$$\tilde{T}_\nu^\mu \equiv s^{\mu\rho} \tilde{\partial}_{\nu\rho} + T_\nu^\mu \quad (4.3)$$

and $T_n^\mu u$ satisfy $gl(n)$:

$$[\tilde{T}_\nu^\mu, \tilde{T}_\sigma^\rho] = \delta_\nu^\rho \tilde{T}_\sigma^\mu - \delta_\sigma^\mu \tilde{T}_\nu^\rho. \quad (4.4)$$

Let J^a be the generators of a finite-dimensional Lie algebra $\mathfrak{g}$ with structure constants f_{ab}^c , i.e.

$$[J^a, J^b] = f_{ab}^c J^c. \quad (4.5)$$

Then $X = X_a(x, s)J^a$ generates an algebra of gerbe gauge transformations, which we call the *gerbe gauge algebra* and denote by $\mathbf{map}(n, p, \mathfrak{g})$. Note that X depends on both the base point x and the surface element s , but ξ only depends on x . The brackets in $\mathbf{vect}(n) \ltimes \mathbf{map}(n, p, \mathfrak{g})$ read

$$\begin{aligned} [\xi, \eta] &= \xi^\mu(x) \partial_\mu \eta^\nu(x) \partial_\nu - \eta^\nu(x) \partial_\nu \xi^\mu(x) \partial_\mu, \\ [\xi, X] &= (\xi^\mu(x) \partial_\mu X_a(x, s) + \partial_\nu \xi^\mu(x) s^{\nu\rho} \partial_{\mu\rho} X_a(x, s)) J^a, \\ [X, Y] &= f^{ab}{}_c X_a(x, s) Y_b(x, s) J^c. \end{aligned} \quad (4.6)$$

Observe the second term in the middle equation, which is absent for ordinary gauge transformations. The Lie derivatives (4.2) and $\mathcal{J}_X = X_a(x, s)J^a$ satisfy the same algebra:

$$\begin{aligned} [\mathcal{L}_\xi, \mathcal{L}_\eta] &= \mathcal{L}_{[\xi, \eta]}, \\ [\mathcal{L}_\xi, \mathcal{J}_X] &= \mathcal{J}_{[\xi, X]}, \\ [\mathcal{J}_X, \mathcal{J}_Y] &= \mathcal{J}_{[X, Y]}, \end{aligned} \quad (4.7)$$

provided that $[T_\nu^\mu, J^a] = 0$.

4.2 Sections and connections

A gerbe section corresponds locally to a tensor field $\phi(x, s)$ valued in a $\mathfrak{g}$ module. If the $gl(n)$ action is given by T_ν^μ and the $\mathfrak{g}$ action by J^a , then ϕ carries the following representation of $\mathbf{vect}(n) \ltimes \mathbf{map}(n, p, \mathfrak{g})$:

$$\begin{aligned} \mathcal{L}_\xi \phi &= -\xi^\mu \partial_\mu \phi - \partial_\nu \xi^\mu s^{\nu\rho} \partial_{\mu\rho} \phi - \partial_\nu \xi^\mu T_\mu^\nu \phi, \\ \mathcal{J}_X \phi &= -X_a J^a \phi. \end{aligned} \quad (4.8)$$

Here and henceforth we suppress arguments, and keep in mind that all fields and functions (ϕ , X_a , etc) depend on (x, s) , except vector fields ξ^μ which only depend on x . It follows immediately from (4.8) that the derivative $\partial_\nu \phi$ transforms as

$$\begin{aligned} \mathcal{L}_\xi \partial_\nu \phi &= -\xi^\mu \partial_\mu \partial_\nu \phi - \partial_\sigma \xi^\mu s^{\sigma\rho} \partial_{\mu\rho} \partial_\nu \phi - \partial_\sigma \xi^\mu T_\mu^\sigma \partial_\nu \phi \\ &\quad - \partial_\nu \xi^\mu \partial_\mu \phi - \partial_\nu \partial_\sigma \xi^\mu s^{\sigma\rho} \partial_{\mu\rho} \phi - \partial_\nu \partial_\sigma \xi^\mu T_\mu^\sigma \phi, \\ \mathcal{J}_X \partial_\nu \phi &= -X_a J^a \partial_\nu \phi - \partial_\nu X_a J^a \phi. \end{aligned} \quad (4.9)$$

Now define the covariant derivative

$$D_\nu \phi = \partial_\nu \phi + A_{a\nu} J^a \phi, \quad (4.10)$$

which is covariant only w.r.t. $\mathbf{map}(n, p, \mathfrak{g})$, and

$$\nabla_\nu \phi = \partial_\nu \phi + \Gamma_{\tau\nu}^\sigma \tilde{T}_\sigma^\tau \phi + A_{a\nu} J^a \phi, \quad (4.11)$$

which is covariant w.r.t. all of $\mathbf{vect}(n) \ltimes \mathbf{map}(n, p, \mathfrak{g})$. The connections $A_{a\nu}(x, s)$ and $\Gamma_{\tau\nu}^\sigma(x, s)$ (which both depend on both x and s) transform as

$$\begin{aligned} \mathcal{J}_X A_{a\nu} &= -f^{bc}{}_a X_b A_{c\nu} + \partial_\nu X_a, \\ \mathcal{L}_\xi A_{a\nu} &= -\xi^\mu \partial_\mu A_{a\nu} - \partial_\sigma \xi^\mu s^{\sigma\rho} \tilde{\partial}_{\mu\rho} A_{a\nu} - \partial_\nu \xi^\mu A_{a\mu}, \end{aligned} \quad (4.12)$$

$$\begin{aligned} \mathcal{J}_X \Gamma_{\tau\nu}^\sigma &= 0, \\ \mathcal{L}_\xi \Gamma_{\tau\nu}^\sigma &= -\xi^\mu \partial_\mu \Gamma_{\tau\nu}^\sigma - \partial_\kappa \xi^\mu s^{\kappa\rho} \tilde{\partial}_{\mu\rho} \Gamma_{\tau\nu}^\sigma - \partial_\kappa \xi^\mu (T_\mu^\kappa \Gamma)_{\tau\nu}^\sigma + \partial_\tau \partial_\nu \xi^\sigma. \end{aligned} \quad (4.13)$$

The consistency of these transformation laws follow immediately because both the covariant derivative and the ordinary derivative transform consistently, and hence so does their difference.

For brevity, we sometimes write $A_\nu = A_{a\nu} J^a$, $\Gamma_\nu = \Gamma_{\tau\nu}^\sigma \tilde{T}_\sigma^\tau$, and $\nabla_\nu = \partial_\nu + \Gamma_\nu + A_\nu$. The associated curvature is

$$[\nabla_\mu, \nabla_\nu] = R_{\mu\nu} + F_{\mu\nu}, \quad (4.14)$$

where

$$\begin{aligned} R_{\mu\nu} &= \partial_\mu \Gamma_\nu - \partial_\nu \Gamma_\mu + [\Gamma_\mu, \Gamma_\nu], \\ F_{\mu\nu} &= \partial_\mu A_\nu - \partial_\nu A_\mu + [\Gamma_\mu, A_\nu] - [\Gamma_\nu, A_\mu] + [A_\mu, A_\nu] \\ &\equiv \nabla_\mu A_\nu - \nabla_\nu A_\mu + [A_\mu, A_\nu]. \end{aligned} \quad (4.15)$$

Note that the derivative of $A_\nu(x, s)$ need covariantization because it is a ($\mathfrak{g}$ -valued) function of both x and s :

$$\nabla_\mu A_\nu = \partial_\mu A_\nu + \Gamma_{\tau\mu}^\sigma s^{\tau\rho} \tilde{\partial}_{\sigma\rho} A_\nu. \quad (4.16)$$

Apart from the ordinary derivative w.r.t. x , we must also covariantize the gerbe derivative $\tilde{\partial}_{\sigma\tau}$. From

$$\begin{aligned} \mathcal{L}_\xi \tilde{\partial}_{\sigma\tau} \phi &= -\xi^\mu \partial_\mu \tilde{\partial}_{\sigma\tau} \phi - \partial_\nu \xi^\mu s^{\nu\rho} \tilde{\partial}_{\mu\rho} \tilde{\partial}_{\sigma\tau} \phi - \partial_\nu \xi^\mu T_\mu^\nu \tilde{\partial}_{\sigma\tau} \phi \\ &\quad - \partial_\sigma \xi^\mu \tilde{\partial}_{\mu\tau} \phi - \partial_\tau \xi^\mu \tilde{\partial}_{\sigma\mu} \phi, \\ \mathcal{J}_X \phi &= -X_a J^a \tilde{\partial}_{\sigma\tau} \phi - \tilde{\partial}_{\sigma\tau} X_a J^a \phi, \end{aligned} \quad (4.17)$$

we see that $\bar{\partial}_{\sigma\tau}\phi$ transforms under $\mathbf{vect}(n)$ as a tensor with two extra indices, but the $\mathbf{map}(n, p, \mathfrak{g})$ action needs compensation. Introduce

$$\Delta_{\sigma\tau}\phi = \bar{\partial}_{\sigma\tau}\phi + B_{a\sigma\tau}(x, s)J^a\phi \equiv \bar{\partial}_{\sigma\tau}\phi + B_{\sigma\tau}\phi. \quad (4.18)$$

It follows that

$$\begin{aligned} \mathcal{L}_\xi B_{a\sigma\tau} &= -\xi^\mu \partial_\mu B_{a\sigma\tau} - \partial_\nu \xi^\mu s^{\nu\rho} \bar{\partial}_{\mu\rho} B_{a\sigma\tau} - \partial_\sigma \xi^\mu B_{a\mu\tau} - \partial_\tau \xi^\mu B_{a\sigma\mu}, \\ \mathcal{J}_X B_{a\sigma\tau} &= -f^{bc}{}_a X_b B_{c\sigma\tau} + \bar{\partial}_{\sigma\tau} X_a. \end{aligned} \quad (4.19)$$

The associated curvature is

$$[\Delta_{\mu\nu}, \Delta_{\sigma\tau}] = \bar{\partial}_{\mu\nu} B_{\sigma\tau} - \bar{\partial}_{\sigma\tau} B_{\mu\nu} + [B_{\mu\nu}, B_{\sigma\tau}]. \quad (4.20)$$

One can also define the “cross curvature” $[\nabla_\mu, \Delta_{\sigma\tau}]$.

4.3 Rescaling invariance

We can use the covariant gerbe derivative $\Delta_{\sigma\tau}$ to impose invariance under surface rescalings. One immediately checks that $s^{\sigma\tau}\Delta_{\sigma\tau}\phi$ and ϕ transform in the same way under $\mathbf{vect}(n) \times \mathbf{map}(n, p, \mathfrak{g})$. Therefore we can consistently impose the constraint

$$s^{\sigma\tau}\Delta_{\sigma\tau}\phi = \lambda\phi \quad (4.21)$$

for any constant λ .

Alternatively, we may consider invariance under rescalings of the surface elements as a symmetry. Consider gerbe sections $\phi(x, s)$ which are invariant under transformations of the form $s^{\mu\nu} \rightarrow f s^{\mu\nu}$. Moreover, we let rescalings depend on the base point x , so infinitesimally $s^{\mu\nu} \rightarrow (1 + F(x))s^{\mu\nu}$ for some function $F(x)$. The *rescaling* $F = F(x)$ satisfies

$$\begin{aligned} [\xi, F] &= \xi^\mu(x) \partial_\mu F(x), \\ [F, G] &= 0, \\ [F, X] &= s^{\mu\nu} F(x) \bar{\partial}_{\mu\nu} X_a(x, s) J^a, \end{aligned} \quad (4.22)$$

in addition to the brackets in (4.6). Eq. (4.7) is supplemented by

$$\begin{aligned} [\mathcal{L}_\xi, \mathcal{R}_F] &= \mathcal{R}_{[\xi, F]}, \\ [\mathcal{R}_F, \mathcal{R}_G] &= 0, \\ [\mathcal{R}_F, \mathcal{J}_X] &= \mathcal{J}_{[F, X]}. \end{aligned} \quad (4.23)$$

In the parlance of constrained systems, $\mathcal{R}_F$ generates a gauge symmetry. The constraint $\mathcal{R}_F = 0$ is first class, which together with the gauge condition (4.21) becomes a second class constraint.

Introduce two generators Λ and $U_{\sigma\tau}^\rho$, satisfying the algebra

$$\begin{aligned} [\Lambda, U_{\sigma\tau}^\rho] &= -2U_{\sigma\tau}^\rho, \\ [\Lambda, T_\sigma^\rho] &= [\Lambda, \Lambda] = [U_{\mu\nu}^\kappa, U_{\sigma\tau}^\rho] = 0, \\ [T_\nu^\mu, U_{\sigma\tau}^\rho] &= \delta_\nu^\rho U_{\sigma\tau}^\mu - \delta_\sigma^\mu U_{\nu\tau}^\rho - \delta_\tau^\mu U_{\sigma\nu}^\rho. \end{aligned} \quad (4.24)$$

Then it turns out that the rescalings can be realized as

$$\mathcal{R}_F = F(x)s^{\mu\nu}\tilde{\partial}_{\mu\nu} + F(x)\Lambda + \partial_\rho F(x)s^{\sigma\tau}U_{\sigma\tau}^\rho. \quad (4.25)$$

To prove that (4.25) indeed furnishes a realization of the rescaling algebra, it is useful to introduce the abbreviations

$$\tilde{\Lambda} = s^{\mu\nu}\tilde{\partial}_{\mu\nu} + \Lambda, \quad \tilde{U}^\rho = s^{\sigma\tau}U_{\sigma\tau}^\rho. \quad (4.26)$$

It is clear that

$$\begin{aligned} [\tilde{\Lambda}, \tilde{U}] &= [\tilde{\Lambda}, \tilde{T}_\sigma^\rho] = [\tilde{\Lambda}, \tilde{\Lambda}] = [\tilde{U}^\mu, U^\nu] = 0, \\ [\tilde{T}_\nu^\mu, \tilde{U}^\rho] &= \delta_\nu^\rho \tilde{U}^\mu, \end{aligned} \quad (4.27)$$

and that we can rewrite (4.25) as

$$\mathcal{R}_F = F(x)\tilde{\Lambda} + \partial_\rho F(x)\tilde{U}^\rho. \quad (4.28)$$

4.4 A special gauge choice

Assume that we require

$$A_{a\mu}(x, s) = A_{a\mu\nu\rho}(x)s^{\nu\rho}, \quad (4.29)$$

where $A_{a\mu\nu\rho} = A_{a\nu\rho\mu} = -A_{a\nu\mu\rho}$. In coordinate-free notation $A = A_{a\mu\nu\rho}dx^\mu dx^\nu dx^\rho J^a$ is a $\mathfrak{g}$ -valued three-form. This choice is obviously not preserved by $\mathbf{map}(n, p, \mathfrak{g})$, but we may hope that it is preserved by the subalgebra generated by X 's of the form

$$X_a(x, s) = X_{a\mu\nu}(x)s^{\mu\nu}. \quad (4.30)$$

The transformation law (4.12) becomes

$$s^{\nu\rho}\mathcal{J}_X A_{a\mu\nu\rho} = -f^{bc}{}_a X_{b\sigma\tau}s^{\sigma\tau}s^{\nu\rho}A_{c\mu\nu\rho} + s^{\nu\rho}\partial_{[\mu}X_{|a|\nu\rho]}, \quad (4.31)$$

where

$$\partial_{[\mu} X_{|a|\nu\rho]} = 2(\partial_{\mu} X_{a\nu\rho} + \partial_{\nu} X_{a\rho\mu} + \partial_{\rho} X_{a\mu\nu}). \quad (4.32)$$

A sufficient condition for this to hold is clearly

$$\mathcal{J}_X A_{a\mu\nu\rho} = -f^{bc}{}_a X_{b\sigma\tau} s^{\sigma\tau} A_{c\mu\nu\rho} + \partial_{[\mu} X_{|a|\nu\rho]}. \quad (4.33)$$

In coordinate-free notation, this reads $\mathcal{J}_X A = [s \cdot X, A] + dX$, where $s \cdot X$ is the contraction of the two-form X and the two-vector s . The associated curvature can now be written

$$F_{\mu\nu}(x, s) = F_{\mu\nu\rho\sigma}(x) s^{\rho\sigma}, \quad (4.34)$$

where $F_{\mu\nu\rho\sigma}$ is totally anti-symmetric in spacetime indices and

$$F_{\mu\nu\rho\sigma} = \partial_{[\mu} A_{\nu\rho\sigma]} + [A_{[\mu\nu\rho}, s^{\kappa\tau} A_{\sigma]\kappa\tau}]. \quad (4.35)$$

In coordinate-free notation, the four-form $F = dA + [A, s \cdot A]$ transforms as $\mathcal{J}_X F = [X, F]$ under $\mathbf{map}(n, p, \mathfrak{g})$.

However, the consistency of (4.29) requires not only (4.33), but it also relies on the assumption that the gauge choice (4.30) defines a subalgebra. One checks that the commutator of two fields of the form (4.30),

$$[X, Y] = s^{\mu\nu} s^{\rho\sigma} X_{a\mu\nu}(x) Y_{b\rho\sigma}(x) f^{ab}{}_c J^c, \quad (4.36)$$

is in general *not* of the same form unless $f^{ab}{}_c = 0$. Hence the choice (4.29) is not invariant even under the subalgebra (4.30) of $\mathbf{map}(n, p, \mathfrak{g})$ if $\mathfrak{g}$ is non-abelian.

4.5 Gerbe holonomy

Let Σ be a closed three-dimensional manifold with local coordinates (σ, τ) , where $\sigma = (\sigma^1, \sigma^2)$. We have thus choosen a foliation of Σ . Now regard Σ as a submanifold $\Sigma \subset \mathbb{R}^n$, with the embedding given by coordinate functions $x^\mu = x^\mu(\sigma, \tau)$. The surface element becomes on Σ

$$s^{\mu\nu} \equiv s^{\mu\nu}(\sigma, \tau) = \epsilon^{ij} \frac{\partial x^\mu}{\partial \sigma^i} \frac{\partial x^\nu}{\partial \sigma^j}. \quad (4.37)$$

If $\mathfrak{g}$ is abelian, we define the holonomy

$$W(\Sigma) = \exp\left(\int_{\Sigma} d^2\sigma d\tau A_{\mu}(x, s) \frac{\partial x^\mu}{\partial \tau}\right). \quad (4.38)$$

One checks that $W(\Sigma)$ is invariant under the gerbe gauge algebra:

$$\begin{aligned}\mathcal{J}_X W &= W(\Sigma) \int_{\Sigma} d^2\sigma d\tau \partial_{\mu} X(x, s) \frac{\partial x^{\mu}}{\partial \tau} \\ &= W(\Sigma) \int_{\Sigma} d^2\sigma d\tau \frac{\partial}{d\tau} X(\sigma, \tau) = 0,\end{aligned}\tag{4.39}$$

since the τ integral vanishes. Diffeomorphism invariance is also clear.

If we make the special gauge choice (4.29), the holonomy becomes

$$\begin{aligned}W(\Sigma) &= \exp\left(\int_{\Sigma} d^2\sigma d\tau A_{\mu\nu\rho}(x) \frac{\partial x^{\mu}}{\partial \tau} \epsilon^{ij} \frac{\partial x^{\nu}}{\partial \sigma^i} \frac{\partial x^{\rho}}{\partial \sigma^j}\right) \\ &= \exp\left(c \int_{\Sigma} d^3x A_{\mu\nu\rho}(x) \epsilon^{\mu\nu\rho}\right) \\ &= \exp\left(c \int_{\Sigma} A\right).\end{aligned}\tag{4.40}$$

since

$$\frac{\partial x^{[\mu}}{\partial \tau} \frac{\partial x^{\nu}}{\partial \sigma^1} \frac{\partial x^{\rho]}}{\partial \sigma^2} = c \epsilon^{\mu\nu\rho} \times \text{Jacobian}\tag{4.41}$$

for some constant c . The holonomy (4.40) is invariant under the restricted set of gauge transformations (4.30), because

$$\mathcal{J}_X W(\Sigma) \propto W(\Sigma) \int_{\Sigma} dX \propto W(\Sigma) \int_{\delta\Sigma} X,\tag{4.42}$$

and the boundary $\delta\Sigma = 0$ by assumption.

Let us now turn to the case $\mathfrak{g}$ non-abelian. In the ordinary one-form gauge theory case, the exponential of the integral must be replaced by the path-ordered integral:

$$W(C) = \mathcal{P} \exp\left(\int_C d\tau A_{\mu}(x(\tau)) \frac{\partial x^{\mu}}{\partial \tau}(\tau)\right),\tag{4.43}$$

where C is some curve. This formal expression is most intuitively defined in the lattice approximation. In particular, $W(C)$ satisfies the relation $W(C_1)W(C_2) = W(C_1 \circ C_2)$, where $C_1 \circ C_2$ is the concatenation of C_1 and C_2 .

Analogously, we now define the surface-ordered integral

$$W(\Sigma) = \mathcal{P} \exp\left(\int_{\delta\Sigma} d^2\sigma d\tau A_{\mu}(x, s) \frac{\partial x^{\mu}}{\partial \tau}\right)\tag{4.44}$$

by its lattice regularization. In particular, $W(\Sigma)$ takes values in the space $V^{\otimes \int_{\delta\Sigma} d^2\sigma}$, which should be thought of as the continuum analogue of (2.5). The size of the space (a continuum tensor product) makes the expression (4.44) merely formal, in contrast to the manifestly well-defined local expressions like (4.10) and (4.15).

4.6 Gerbe Yang-Mills theory

In this subsection we assume that there is a preserved constant (and thus flat) metric $g_{\mu\nu}$ with inverse $g^{\mu\nu}$, and hence that diffeomorphism invariance is broken down to Poincaré invariance. This means that $\Gamma_{\tau\nu}^\sigma = 0$, so we can ignore the difference between the covariant derivatives D_ν and ∇_ν (4.10), (4.11).

The natural gerbe generalization of the pure Yang-Mills action is

$$S = \frac{1}{2} \int d^n x \int d^2 s F^{a\mu\nu}(x, s) F_{a\mu\nu}(x, s), \quad (4.45)$$

which leads to the Yang-Mills equations

$$D_{a\nu} F^{a\mu\nu}(x, s) = 0. \quad (4.46)$$

In particular, if we assume that the connection is of the form (4.29), we recover the equations of motion of $(p+1)$ -form electromagnetism in the abelian case:

$$s_{\rho\sigma} \partial_\nu F^{\mu\nu\rho\sigma}(x) = 0. \quad (4.47)$$

The gerbe equations (4.46) are thus the natural non-abelian generalization of $(p+1)$ -form electromagnetism.

4.7 The classical Yang-Baxter equation

In the previous subsections all formulas were specialized to the case $p = 2$, but the analogous formulas for arbitrary p are readily deduced. We here set $p = 1$, so the line coordinate $s = (s^\mu)$ becomes a one-vector. If we make the gauge choice analogous to (4.29), so the connection is given by a two-form $A_{\mu\nu}(x)$, the curvature three-form becomes

$$F_{\mu\nu\rho}(x) = \partial_{[\mu} A_{\nu\rho]}(x) + [A_{[\mu\nu}(x), s^\sigma A_{\rho]\sigma}(x)]. \quad (4.48)$$

This gauge choice is of course completely non-invariant.

Let $A_{\mu\nu}(x)$ be spatially homogeneous, i.e. it does not depend on x at all, so the first term above vanishes. Moreover, consider the special point $s = (1, 1, 1)$ in three dimensions. The zero-curvature condition $F_{\mu\nu\rho} = 0$ then explicitly becomes

$$\begin{aligned} [A_{12}, A_{31} + A_{32}] + [A_{23}, A_{12} + A_{13}] + [A_{31}, A_{21} + A_{23}] &= \\ -2([A_{12}, A_{13}] + [A_{12}, A_{23}] + [A_{13}, A_{23}]) &= 0. \end{aligned} \quad (4.49)$$

This is recognized as the classical Yang-Baxter equation (CYBE). That this equation arises in the continuum formulation is hardly surprising since we have seen that the QYBE appears on the lattice.

As is well known, the CYBE is an equation on the triple space $V^{\otimes 3} = V_1 \otimes V_2 \otimes V_3$, where V is a vector space associated to a link, and $A_{\mu\nu}$ acts non-trivially on $V_\mu \otimes V_\nu$ only: $A_{12} = A \otimes \text{id}$, etc. The simplest class of solutions are the trigonometric ones of the form

$$A(u, v) = \frac{1}{u - v} J^a \otimes J_a, \quad (4.50)$$

where J^a are the generators of $\mathfrak{g}$ and we have contracted indices using the Killing metric on $\mathfrak{g}$. Note that the solution depends on additional, “spectral” parameters. If we collect these into a vector $u = (u_1, u_2, u_3)$ we may write

$$A_{12}(u) = \frac{1}{u_1 - u_2} J^a \otimes J_a \otimes \text{id}, \quad (4.51)$$

etc.

Returning to $p = 2$, vanishing of the curvature four-form (4.35), $F_{\mu\nu\rho\sigma} = 0$, becomes in the spatially homogeneous case and at the point $s^{12} = s^{13} = s^{14} = s^{23} = s^{24} = s^{34} = 1$:

$$\begin{aligned} [A_{123}, A_{124}] + [A_{123}, A_{134}] + [A_{123}, A_{234}] &+ \\ [A_{124}, A_{134}] + [A_{124}, A_{234}] + [A_{134}, A_{234}] &= 0. \end{aligned} \quad (4.52)$$

This is the infinitesimal form of Zamolodchikov’s tetrahedron equation [4, 8, 7, 28]. It is an equation in the space $V^{\otimes 6} = V_{12} \otimes V_{13} \otimes V_{14} \otimes V_{23} \otimes V_{24} \otimes V_{34}$, such that $A_{\mu\nu\rho}$ acts trivially on all spaces except $V_{\mu\nu} \otimes V_{\mu\rho} \otimes V_{\nu\rho}$.

The classical tetrahedron equation (4.52) has a rather disquieting property. Of the six terms, the only one that is non-trivial on all factors except V_{34} is $[A_{123}, A_{124}]$. Therefore, this expression can in fact not act non-trivially on all of $V_{12} \otimes V_{13} \otimes V_{14} \otimes V_{23} \otimes V_{24}$, but it rather consists of terms that act on

four spaces only. The natural ansatz is $A_{123} = B_{12} + B_{13} + B_{23}$, where $B_{\mu\nu}$ is a solution of the Yang-Baxter equation. I am not aware of any genuine solutions to (4.52).

The generalization to higher order is obvious.

4.8 Abelian extensions

Upon quantization, we expect the gerbe gauge algebra to acquire an abelian extension. To construct representations of such extensions following [17], we introduce a one-dimensional closed curve $x^\mu = q^\mu(t)$, $s^{\mu\nu} = \varsigma^{\mu\nu}(t)$, where $t \in S^1$, and expand all fields in a Taylor around $(x, s) = (q(t), \varsigma(t))$:

$$\phi(x, s) = \sum_{\substack{|\mathbf{m}|, |\mathbf{r}| \\ |\mathbf{m}+\mathbf{r}| \leq p}} \frac{1}{\mathbf{m}!\mathbf{r}!} \phi_{\mathbf{m}\mathbf{r}}(t) (x - q(t))^{\mathbf{m}} (s - \varsigma(t))^{\mathbf{r}}, \quad (4.53)$$

where $\mathbf{m} = (m_1, \dots, m_n)$ and $\mathbf{r} = (r_{11}, \dots, r_{nn})$, all $m_\mu \geq 0$, $r_{\mu\nu} \geq 0$ ($\nu < \mu$) are multi-indices of length $|\mathbf{m}| = \sum_{\mu=1}^n m_\mu$ and $|\mathbf{r}| = \sum_{\mu=1}^n \sum_{\nu=1}^\mu r_{\mu\nu}$, respectively. Moreover,

$$(x - q(t))^{\mathbf{m}} = (x^1 - q^1(t))^{m_1} \dots (x^n - q^n(t))^{m_n}, \quad (4.54)$$

and similar for $(s - \varsigma(t))^{\mathbf{r}}$.

After introducing canonical momenta for $q^\mu(t)$, $\varsigma(t)$ and $\phi_{\mathbf{m}\mathbf{r}}(t)$ and normal ordering, we obtain Fock representations of the following algebra:

$$\begin{aligned} [\mathcal{L}_\xi, \mathcal{L}_\eta] &= \mathcal{L}_{[\xi, \eta]} + \frac{1}{2\pi i} \int dt (c_1 \partial_\nu \dot{\xi}^\mu(t) \partial_\mu \eta^\nu(t) + c_2 \partial_\mu \dot{\xi}^\mu(t) \partial_\nu \eta^\nu(t)), \\ [\mathcal{L}_\xi, \mathcal{J}_X] &= \mathcal{J}_{[\xi, X]}, \\ [\mathcal{J}_X, \mathcal{J}_Y] &= \mathcal{J}_{[X, Y]} + \frac{k}{2\pi i} \int dt \dot{X}_a(t) Y_b(t) \delta^{ab}, \end{aligned} \quad (4.55)$$

where δ^{ab} is the Killing metric in $\mathfrak{g}$ and

$$\begin{aligned} \partial_\nu \dot{\xi}^\mu(t) &\equiv \dot{q}^\rho(t) \partial_\nu \partial_\rho \xi^\mu(q(t)), \\ \dot{X}_a(t) &\equiv \dot{q}^\mu(t) \partial_\mu X_a(q(t), \varsigma(t)) + \dot{\varsigma}^{\mu\nu}(t) \partial_{\mu\nu} X_a(q(t), \varsigma(t)). \end{aligned} \quad (4.56)$$

Equation (4.55) is the gerbe analogue of the Virasoro and affine Kac-Moody algebras, and the abelian charges c_1 , c_2 and k can be computed with the methods of [17].

5 Conclusion

In this paper I have developed a local continuum formulation of the p -form lattice gauge theory in Section 2. Holonomy is an integral over p -dimensional Wilson submanifolds, as in (2.5) and (4.44), making this theory closely related to $(p - 1)$ -gerbes. However, there are some advantages compared to other formulations:

- A natural covariant derivative exists.
- There is only a p -form connection, not a hierarchy of connections.
- The relation to integrability, i.e. the quantum and classical Yang-Baxter equations, is clear.

The main advantage compared to formulations in loop space is manifest locality, which should facilitate explicit calculations.
